Recurrent Neural Networks for Range-only SLAM

Hyungtae Lim[1] , Junseok Lee[1], Changgyu Park[1], Ye Eun Kim[1],

Abstract— **Range-only SLAM is a method for localizing a mobile robot and beacons by mainly utilizing distance measurements. Unlike the traditional probability-based range-only SLAM method, we present a novel approach using a recurrent neural network architecture that directly learns the end-to-end mapping between distance data and robot position.**

I. INTRODUCTION

Trilateration is a conventional algorithm for locating a vehicle in the metropolitan area by range measurements between the vehicle and fixed beacon sensors. [1]. Due to the convenience of trilateration that estimates the position of a receiver of range sensors if one only knows range measurement, trilateration algorithm has been widely incorporated into robotics fields, especially utilized in the indoor environment to estimate the position of an object by distance measurements obtained from range sensors such as UWB, ultrasonic, laser-based beacon sensors [2]–[4]. Specifically, range-only Simultaneous Localization and Mapping(RO-SLAM) methods are utilized popularly, which not only estimate the position of the receiver of range sensors, but also localize the position of range sensors regarded as features on a map, and studies have been conducted continuously in terms of probability-based approach [5]–[8].

In the meantime, as deep learning age has come [9], various kinds of deep neural architectures have been proposed for many tasks related to robotics field, such as detection [10]–[12], navigation [13], [14], pose estimation [15], and so on. Especially, recurrent neural networks (RNNs), originated from Natural Language Process(NLP) area [16], have been shown to achieve better performance in case of dealing with time variant information, thereby RNNs are widely utilized such as not only speech recognition, but also pose estimation and localization [15], [17]–[20].

In this paper, we propose a deep learning-based localization method by stacked bidirectional Long Short-Term Memory(stacked Bi-LSTM) for more accurate localization of the robot. Using deep learning, our structure directly learns the end-to-end mapping between range measurements and robot position. This operation non-linearly maps the relationship not only considering the long-range dependence of sequential distance data by the LSTM, but also using the correlation of the backward information and the forward information of the sequence of each time step by virtue of its bidirectional architecture.

II. RELATED WORKS

In this section, we briefly survey previous researches closely focused on Long Short-Term Memory(LSTM) model and applications of LSTMs to solve domain problems.

1) LSTM: LSTM is a type of Recurrent Neural Networks(RNNs) that has loops so that infer output based on not only the input data, but also the internal state formed by previous information. In other words, while the RNN deals with sequential data, the network has remembered the previous state generated by past inputs and might be able to output the present time step via internal state and input, which is very similar to filtering algorithms.

However, RNNs often have a *vanishing gradient problem*,i.e., RNNs fail to propagate the previous matter into present tasks as time step gap grows by. In other words, RNNs are not able to learn to store appropriate internal states and operate on long-term trends. That is the reason why the Long Short-Term Memory (LSTM) architecture was introduced to solve this long-term dependency problem and make the networks possible to learn longer-term contextual understandings [21]. By virtue of the LSTM architecture that has memory gates and units that enable learning of long-term dependencies [22], LSTM are widely used in most of the deep learning research areas and numerous variations of LSTM architecutres have been studied.

2) Deep Learning for SLAM:

3) Applications of LSTMs: There are many variations of LSTM architecture. As studies of deep learning are getting popular, various modified architectures of LSTM have been proposed for many tasks in a wide area of science and engineering. Because LSTM is powerful when dealing with sequential data and infering output by using previous inputs, LSTM is utilized to estimate pose by being attached to the end part of deep learning architecture [18]–[20] as a stacked form of LSTM. In addition, LSTM takes many various data as input; LSTM is exploited for sequential modeling using LiDAR scan data [17], images [15], [18], IMU [23], a fusion of IMU and images [24].

III. Experiment

We set the experiment on the virtual situation and generate distance data set which corresponds to the position with 10% noise error and let RNN be trained using these distance data. Train data are just zigzag paths and test data is an arbitrary path, so we also check if RNN can estimate the position despite the variation of distance data as input.

Let Θ be the parameters of our RNN model, then our final goal is to find optimal parameters Θ^* for localization by minimizing Mean Square Error (MSE) of Euclidean distance between ground truth position Y_k and estimated position $\hat{Y}_k$.

$$\Theta^* = \underset{\Theta}{\operatorname{argmin}} \sum_{k=1}^{N} \parallel Y_k - \hat{Y}_k \parallel^2 \tag{1}$$

V. Conclusions

We suggested a novel approach to range-based localization using recurrent neural network models. Results show that the RNN-based localization can reduce position error. As a future work, RNNs need to be tested in the real-world
